

2020 Arctic Wildfires Emissions So Far Surpass All of 2019

August 31, 2020

Wildfires in the Arctic have emitted more carbon dioxide so far in 2020 than in all of 2019, according to European atmospheric composition data cited by The Guardian newspaper on Monday.

As much as 245 megatons of CO₂ have been released from Arctic wildfires up to Aug. 24 this year, compared with 181 megatons in the whole of 2019.

That's an increase of 35% and may be setting a new precedent, Mark Parrington, senior scientist at the EU's Copernicus atmosphere monitoring service, [told](#) The Guardian.

"In some respects [the data] has been similar to 2019 in terms of the dry and warm conditions in the Siberian Arctic. This year, the difference was a large cluster of fires that burned through July for many days leading to higher estimated emissions," Parrington said.

Around 600 active fires have been observed in the region in late July, compared with 400 in 2019 and about 100 on average between 2003–2018, according to the data.

Some 205 megatons of the CO₂ emitted so far this year was released in June and July

“We have seen two years of anomalously high activity, according to the satellite record that goes back to 2003,” Thomas Smith, assistant professor of environmental geography at the London School of Economics, told The Guardian.

Russian weather officials and environmentalists have said climate change is a major factor behind the increase in fires. European climate scientists have attributed the resurgence of wildfires to freakishly warm weather across vast parts of Siberia combined with low soil moisture.

Boreal wildfire season typically peaks in July and August.

Russia, the world's fourth-largest greenhouse gas emitter whose economy heavily depends on oil and gas, has been slow to take steps to reduce its carbon emissions.

Recent studies have forecast the loss of summertime ice cover in the Arctic by 2050 even if current levels of CO₂ emissions were significantly cut.
